Figure Legend

A 88-year-old male who has had medical problem of end-staged renal disease on regular hemodialysis maintenance for years. He began to suffer from fever and general malaise since 2 days ago before emergent department visit. Leucopenia (220/uL), thrombocytopenia (5000/uL) and hypotension were detected. The chest X-ray was unremarkable and the urine routine report was not available because of the oliguria. Under the impression of septic shock, he was admitted to intensive care unit. In the next 2 days, the bicytopenia and lactic acidosis persisted even with broad-spectrum regimen of antibiotic therapy. Low abdominal pain was complained by patient and the bedside-sonography revealed distended bladder. Three-way foley catheter was inserted with pus-like urine found. Computed tomography of abdomen was performed soon and air-bubbles found in the urinary bladder. Emphysematous cystitis was confirmed and blood culture concluded Klesiella pneumonia bacteremia.
