摘要內容

Mirizzi's syndrome, a rare complication of cholelithiasis, presents as a formidable diagnostic and therapeutic challenge. We herein describe a case of Mirizzi's syndrome type III in order to highlight the role of pre-operative diagnosis and treatment with the use of endoscopic retrograde cholangiopancreatography (ERCP). The patient underwent endoscopic nasobiliary drainage (ENBD) before laparoscopic choledocholithotripsy and cholecystectomy. Pre-operative ERCP acts as a temporizing method to relieve obstructive jaundice or cholangitis before surgery is available, and is highly favored as it enables the surgeon to identify and minimize iatrogenic bile duct injury during operation.
