Pulmonary barotrauma and decompression sickness are serious complications of scuba diving, caused by an inappropriate ascent. For diving abroad, strict surface interval requirement for flying after diving has been recommended by U.S. navy diving manual. We herein report a rare case of an experienced scuba diver who had a severe dyspnea on the homecoming international flights after diving vacation abroad. Repeated ambient pressure changes during two flight transfers led the diving complication into an impending tension pneumothorax at the terminal. The patient recovered well after tube thoracotomy and blebectomy.
