Abstract:

Dermatomyositis (DM) and polymyositis (PM) are idiopathic inflammatory myopathies characterized by inflammation of the skin and muscles and proximal skeletal muscle weakness. Previous epidemiological studies have shown an increased rate of cancer in people with dermatomyositis and polymyositis. The epidemiologic data on IIM-associated cancer types included adenocarcinomas of the cervix, lung, ovaries, pancreas, bladder, stomach, as well as hematologic cancers including non-Hodgkin's lymphoma and Hodgkin's lymphoma. We presented one 31-year-old woman had disclosed endocervix clear cell carcinoma within the first the first year of diagnosis of polymyositis.
